Applications

Regenerative circuits are used to provide faster cylinder extension speeds by taking the oil from the rod end and diverting it to the head end of the cylinder. This means that the effective area during extension is only the rod area that gives a faster speed but also a reduced force. This means using a cylinder with a 2:1 area ratio between piston and rod, equal speeds and forces can be obtained in both directions without using a double rod.

Sun offers two types of regenerative valve assemblies. One provides full time regeneration and the other is a pressure sensitive regenerative circuit. The full time regeneration has only a limited number of applications and is most commonly used for providing fast extension speeds with low force.

The pressure sensitive regenerative circuit is used in many applications such as compacting machines. The first part of the cylinder extension occurs when there is very little load (for example during initial compaction) and regeneration provides a faster speed. When the load resistance increases, the pressure on the full bore side starts to increase and will pilot open a counterbalance valve connecting the rod side to tank and take the circuit out of regeneration. This then provides a slower speed, as it is now operating on the full bore area, but also a corresponding increase in force. Regenerative circuits do not affect the retraction of the cylinder.

It is important to remember to size pipe work correctly to allow for the increased flow going into the full bore side of the cylinder.

The circuit Sun uses for all types of regeneration includes a pilot to close check valve connecting from the rod side to the full bore side. If this circuit is used in applications where the load can extend the cylinder it will be necessary to incorporate a vented load control valve on the rod side to prevent the load running away.

The illustration shows the appropriate calculations for regenerative circuits.

Design Concepts and Features

The first main feature of all Sun regenerative packages is that they are installed after the directional valve controlling the actuator. This means that the higher flows generated are not passed through the directional valve, which can be the same size as for normal circuits. This also means that this package can more easily be added to an existing circuit with the minimum of disruption.

The main feature for the pressure sensitive regenerative circuit is that Sun uses a counterbalance valve to transfer from regeneration to normal operation. This type of valve opens gradually as the pilot pressure increases and gives a much smoother transition compared to the more commonly used sequence valve. It therefore eliminates a great deal of the shock, which can occur during this transition.

The assemblies can be supplied for various flow rates and packages such as line mounted, ISO sandwich assemblies and gasket-mounted subplates. It is also possible to mount the cartridges directly into the cylinder head.
Standard Assemblies: Line Mounted Regenerative Assemblies

PRESSURE SENSITIVE REGENERATION APPLICATIONS

REGENERATION

15 GPM Maximum Regenerative Flow
